-----END RSA PRIVATE KEY-----

```

Expected items in the private key:

The RSA private key should contain the following with the 10th item being optional:

- | | |
|---------------------|----------------------------------|
| 1. Version | version (the version number) |
| 2. Modulus | integer - - n |
| 3. publicExponent | integer - - e |
| 4. privateExponent | integer - - d |
| 5. Prime1 | integer - - p |
| 6. Prime2 | integer - - q |
| 7. Exponent1 | integer - - d mod (p - 1) |
| 8. Exponent2 | integer - - d mod (q - 1) |
| 9. Coefficient | integer - - (inverse of q) mod p |
| 10. otherPrimeInfos | otherPrimeInfos OPTIONAL |

Note: The 10th otherPrimeInfos is only required for version 1

To decode the file I utilized the website <https://lapo.it/asn1js/>. The following text is what is the output.

The following data will be typed up as

1. Label
2. Offset
3. Length
4. Value

5. DER encoding

The decoding of the file begins by notifying that there are 9 elements in the sequence.

1. Sequence
2. 0
3. $4 + 1764$
4. (9 elems)

It should also be noted that this sequence is labeled as (constructed).

Version

Next, we are given the version, as the value is 0 this means we will not need the otherPrimeInfos:

1. INTEGER
2. 4
3. $2 + 1$
4. 0
5. 02 01 00

Explanation of DER Encoding for one sequence:

The 02 in binary stands for 0000 0010 this is the type and the beginning of the object the tag class begins with 00 . Then the p/c which states that is primitive with the 0. The 01 is the length in octets of the value and lastly the 00 is the value.

Modulus

1. INTEGER
2. 7
3. $4 + 385$

4. 3073 bit

```

```

According to the RFC 8017, we are supposed to find the following in the public key:

- n the RSA modulus, a positive integer
- e the RSA public exponent, a positive integer

When I attempt to put the contents into the decode we receive the error “Length over 48 bits not supported at position 1” to fix this we must in the kali terminal type out
ssh-keygen -f id_rsa_homework.pub -e -m pem

To then get a file that is able to decoded:

-----BEGIN RSA PUBLIC KEY-----

```
MIIBigKCAYEAuDqcbLs+WQguWieh6nankrqr5DjiDP0IB1UNW1Zd6SfniCPRikQc

```

5. 02 82 01 81

Public Exponent

1. INTEGER
2. 393
3. 2+3
4. 65537
5. 02 03

I want to note that the modulus and the publicExponent are the same for the public and private key which is to be expected to be able to perform the RSA calculations.

–Sanity Check–

We must use RSA formulas to do a sanity check. It is important to acknowledge that the private and public keys match the n and e . I used the formula $\lambda(n) = \text{lcm}(p - 1, q - 1)$, where λ is $e * d \bmod \lambda(n) = 1$ and lastly $\text{gcd}(e, \lambda(n)) = 1$. I also verified that n

$= p * q$. In the SSH file you will also be able to find the python code used to check such integer value
